(54) Method of reducing trash recirculation in open-end spinning machines

(57) A method of reducing trash recirculation into the fiber formation stream of an open-end spinning machine yarn formation station of an open-end spinning machine (1) of the type having a movable trash belt (18) which collects trash removed from sliver during yarn formation, said spinning machine (1) having a predetermined, relatively high, conventional trash belt speed, comprising the steps of moving the trash belt (18) at a low speed determined by the type of trash contained in the fiber, the type of yarn being spun and the type of fabric to be formed from the yarn, but in no event more than 50 percent of the conventional trash belt speed. The low speed of the trash belt (18) is between 15 and 40 percent of conventional trash belt speed, with the low speed increasing as the proportion of heavy to light trash in the trash mixture increases. The low speed of the trash belt (18) is varied a further plus or minus 10 percent of the conventional trash belt speed, the low speed being increased up to 10 percent for heavy yarn containing heavy trash and the low speed being decreased up to 10 percent for fine yarns containing light trash with proportional variation in the percentage of increase of decrease proportional to the range of yarn size. The low speed of the trash belt (18) is altered when needed to accommodate changes in trash mixture content, yarn size and yarn trash content being processed on the machine. The trash is cleaned from the trash belt (18) as the trash belt (18) moves at the low trash belt speed.

FIG. 2

EP 0 893 518 A2

Description

This invention relates to methods of reducing trash recirculation in open-end spinning machines.

In the open-end spinning process the fibers to be spun into a yarn on the machine are removed from a sliver supplied to the machine, separated, and then spun into a yarn in the rotor or other yarn-producing mechanism. Each machine contains numerous adjacent stations. The opening of the sliver into individual fibers occurs in opening devices of varying types which reside in upstream fiber-flow proximity to the rotor. Typically, an opening roller having spikes or sawteeth on its circumference rotates in the opening device. It is these spikes or sawteeth that comb or tease the fibers out of the sliver.

At the input end of the station the sliver is drawn from a sliver can or bobbin into the opening device by a feed roller. An intake opening guide plate is pressed against the feed roller with a predetermined spring force. The trash contained in the sliver, which may include dust, seeds, insect fragments and neps, is forced out of the sliver by the opening roller and is physically separated from the fibers.

Trash content varies in type and quantity depending on where the cotton was grown, the growing season and the price of cotton. Heavy trash, sometimes known as "pepper trash", usually comprises crushed cotton seeds, plant stems, and any other hard raw material which might be processed in the early cleaning stages of the cotton. Usually, some quantity will remain up carding. Medium trash comprises pulverized leaves, dirt and twigs. Light trash is made up of dust, short and immature fibers, smaller variations of both heavy and medium trash and other natural impurities.

The density of the trash is relatively high in comparison with the density of the fibers. The trash therefore gains greater kinetic energy than the fibers as the fibers and trash are carried into the radial outer region of the gap between the opening roller and housing wall. This tends to separate the trash from the fiber by centrifugal force as the trash moves outwardly at a greater rate and with greater energy than the fibers.

A discharge opening is located below the opening roller through which the trash falls. The trash is collected on a moving endless trash belt which is intended to carry the trash to one end of the machine, where a cleaning element, such as a brush roller, removes the trash from the belt. The cleaned belt rotates continually, so that each area of the belt alternates through successive trash-accumulating and trash-cleaning cycles.

Ideally, the belt has a fibrous nap to which the trash clings until it reaches the trash removal area at one end of the machine. However, after a relatively short period of time the belt becomes worn and progressively less able to physically retain the trash on its surface along the length of the machine. Vibration, air currents and other conditions can therefore cause some of this loose trash on the belt to be sucked back into the discharge opening or other access opening of a downstream station as the trash is carried along the length of the machine towards the trash removal area.

Reintroduction of trash into the fiber stream can cause the yarn to break or form slubs, which is usually sensed by stop-motion devices on the machine. At this point, the yarn must be pieced up either manually or automatically. This clearly reduces machine efficiency by stopping the output of yarn from the station until piece-up is completed. Even smaller trash which does not cause the yarn to break decreases the quality of the yarn by reintroducing trash into the yarn.

It has been noticed in the mill environment that during times of belt stoppage due to malfunction, machine efficiency increased somewhat, but to applicants' knowledge the reason for this was not appreciated. Applicants also believe that for a time the trash belt of a Schlafhorst SE-9 was manually stopped by overriding safety circuits in recognition that machine efficiency increased somewhat. To applicants' knowledge, this practice was abandoned because operators either forgot to stop the belt at the proper intervals or, after stopping them, forgot to restart them.

In addition, applicants are aware of at least one machine that was equipped for a short period of time with a single phase to three phase AC inverter which was capable of varying the trash belt speed, but which did not work satisfactorily, was not supported by the machine manufacturer, was removed and its use abandoned.

The invention according to this application represents a satisfactory and cost-effective solution to the problems described above. The practice of the invention can be varied within wide parameters to take into account mill conditions, sliver quality and trash content, machine and trash belt age and condition. Empirical use of the invention permits optimized operation of the open-end machine and high quality yarn without increased cost.

According to this invention there is provided a method of reducing trash recirculation into the fiber formation stream of an open-end spinning machine yarn formation station of an open-end spinning machine of the type having a movable trash belt which collects trash removed from sliver during yarn formation, said spinning machine having a predetermined, relatively high, conventional trash belt speed, comprising the steps of moving the trash belt at a low speed determined by the type of trash contained in the fiber, the type of yarn being spun and the type of fabric to be formed from the yarn, but in no event more than 50 percent of the conventional trash belt speed.

Preferably, the low speed of the trash belt is between 15 and 40 percent of conventional trash belt speed, with the low speed increasing as the proportion of heavy to light trash in the trash mixture increases. The low speed of the trash belt may be varied a further plus or minus 10 percent of the conventional trash belt speed, the low speed being increased up to 10 percent for heavy yarn containing heavy trash and the low speed being decreased up to 10 percent for fine

yarns containing light trash with proportional variation in the percentage of increase or decrease proportional to the range of yarn size. The low speed of the trash belt may be altered when needed to accommodate changes in trash mixture content, yarn size and yarn trash content being processed on the machine. The trash may be cleaned from the trash belt as the trash belt moves at the low trash belt speed.

In one embodiment, the low speed of the trash belt may be between 5 and 50 percent of the conventional trash belt speed. The low speed of the trash belt is preferably between 20-30 percent of the conventional trash belt speed. More preferably the low speed of the trash belt is between 15-25 percent of the conventional trash belt speed.

In another embodiment of the invention, the low speed of the trash belt may be between 25-35 percent of the conventional trash belt speed. Preferably, the said low speed of the trash belt is between 30-40 percent of the conventional trash belt speed.

The method may also include the steps of providing a motor for controlling the rate of movement of the trash belt.

Preferably, the step of providing a motor for controlling the rate of movement of the trash belt comprises the step of controlling the speed of rotation of the motor by applying a variable frequency to the motor.

Therefore, it is an advantage of a preferred embodiment of the invention that it provides a low-speed trash belt for an open end spinning machine and method which increases open-end spinning machine efficiency.

It is another advantage of a preferred embodiment that it provides a low-speed trash belt for an open end spinning machine and method which increases the quality of the yarn being spun on the open-end spinning machine.

It is another advantage of a preferred embodiment that it provides a low-speed trash belt for an open end spinning machine and method which reduces the ambient dust level in the area of the open-end spinning machine.

It is another advantage of a preferred embodiment that it provides a low-speed trash belt for an open end spinning machine and method which can utilize a "soft start" to prevent trash on the belt from being vibrated or shaken loose and reintroduced into adjacent air currents.

It is another advantage of a preferred embodiment that it provides a low-speed trash belt for an open end spinning machine and method which increases the life and maintenance intervals of the trash belt, belt motor, pulleys and other moving parts.

At least one embodiment of the invention will now be described by way of example only, with reference to the accompanying drawings, in which:

Figure 1 is a simplified perspective view of an open-end spinning machine;

Figure 2 is a cross-sectional view of an opening device on an open-end spinning machine of the type with which the invention is practiced;

Figure 3 is a view according to Figure 1 with parts broken away to expose the trash belts and the motor drive for the trash belts;

Figure 4 is a schematic diagram showing the trash belt, motor and controller; and

Figures 5-9 are tables plotting several examples of velocity and time profiles according to various embodiments of the invention.

The preferred embodiments of this invention concern low-speed trash belts for open-end spinning machines and methods of controlling the speed of the trash belt of open-end spinning machines. As described below, careful control of the rate of movement of the trash belt improves both machine efficiency and yarn quality.

Referring now specifically to the drawings, a conventional open-end spinning machine according to the present invention is illustrated in Figure 1 and shown generally at reference numeral 1. For purposes of illustration the invention is described with reference to a Schlafhorst Model SE-9 open-end spinning machine, broadly illustrated in Figure 1. However, the invention is equally applicable to other machines which utilize trash belts to carry away trash removed from the sliver during yarn formation on the machine.

Spinning machine 1 includes numerous adjacent spinning stations 2 along the length of both sides of the machine.

Referring now to Figure 2, each station 2 includes an opening device 10, which includes a housing 11 with an intake opening 12 for the sliver being formed into yarn. A trash discharge passage 13 and a fiber feeding opening 14 for feeding the separated fibers to the spinning rotor, not shown, through a fiber guide passage 15 is formed within walls 16 and 17. The trash discharge passage 13 extends downwardly and opens directly above a trash belt 18. Trash belt 18 is an endless conveyer-type belt which moves successively through a cycle where trash is deposited onto its surface and a cleaning cycle where a brush or other device, not shown, removes the trash for disposal. The trash belt 18 may be driven by its own motor, as in the Schlafhorst SE-9, or may be driven by the main machine drive, as in the Schlafhorst SE-8.

A sliver feed roller 19, which rotates in a clockwise direction draws a sliver "S" under a compressor plate 21 through a movable intake opening guide plate 22 into the intake opening 12 of the housing 11. The intake opening guide plate 22 is pivotally supported on the housing wall by a pin 23 and urged by a spring 24 against the sliver feed roller 19.

In the housing 11, an opening roller 25 rotates in a counterclockwise direction on a shaft 26 which is supported in

the housing 11. On its circumference, the opening roller 25 has an array of sawtooth-like combing elements 27 formed in a predetermined pattern on its outer circumference. These combing elements 27 comb individual fibers out of the sliver "S" as it is passed from under the sliver feed roller 19 into contact with the opening roller 25.

As a result of airflow induced in the housing 11, the separated fibers are entrained by the air flow and carried through the fiber guide passage 15 to the spinning unit. The trash "T" expelled from the stream of individual fibers normally has a greater density than the fibers and is therefore expelled centrifugally from the fibers into the trash discharge passage 13.

Note in Figure 2 that the wall 16 is separated from the intake opening guide plate 22 by an opening 29. It has been determined that loose trash on the trash belt 18 can be reintroduced through this opening 29, through the trash discharge opening 13 or through other spaces back into the airflow within which the cleaned, separated fiber is moving in the fiber feeding opening 14. This is believed to occur as the result of the trash belt 18 moving along the length of the open-end spinning machine during machine operation, as described above.

Trash types and quantity in the cotton determines the speed at which the trash belt is optimally moved in order to obtain the highest practicable efficiency. The efficiency is also affected by having to remove yarn slubs or thick yarn sections, and having end breaks due to thin yarn with low tensile strength. Yarn trash is by far the leading factor in these inconsistencies.

Using as a base point that most SE-6 trash belts run normally at approximately 40-45 m/m and SE-9 trash belts run normally at approximately 60-65 m/m, machine efficiencies can be improved by running the belts at slower speeds. In general, speed variations should not extend outside of 5-50% of normal trash belt operating speed.

In accordance with the invention, therefore, the trash belt 18 is controlled in several ways calculated to minimize reintroduction of trash into the fiber formation areas of the opening device 10.

Referring now to Figure 3, the trash belts 18 of the open-end spinning machine 1 extend down the length of the machine frame from one end to the other. In the particular embodiment of open-end spinning machine used in this application for purposes of illustration, both belts 18 are driven by a single motor 30 through drive and driven pulleys 31 and 32 rotatably connected by a drive belt 33. The other belt 18 is rotated by a solid concentric shaft 35 extending from one belt 18 to the other. A typical motor 30 used for this application is a 1/3 HP constant frequency, 1750 rpm, 60 Hz, 3-phase AC motor.

Conventional machine operation requires that the belts 18 rotate continuously at a relatively high rate of travel, on the order of 59-60 meters per minute. The Schlafhorst SE-9 does not have a "Stop/Start" control for the trash belts 18. Rather, a safety circuit must be overridden.

In accordance with a preferred embodiment of the invention, Figure 4 illustrates that an adjustable frequency drive, or inverter, 37, is wired to the motor 30. A suitable inverter 37 is the General Electric AF-300 family of inverters, selected according to conventional selection criteria to match the particular motor 30 being controlled.

Inverter 37 is equipped with a control keypad which permits frequency selection, timing values and other status conditions. Such inverters 37 can dwell for up to 6,000 seconds, or 100 minutes. This permits a very wide range of speeds and time intervals between belt 18 movement cycles.

Alternatively, motor 30 can be controlled by controlling only voltage to the motor, or with a combination of voltage and frequency variation.

Inverter 37 can thus control the belts 18 in various ways. Several of these are shown in Figures 5-9, where time is plotted horizontally and velocity of the belts 18 vertically. For example, in Figure 5 a "soft start" and "soft stop" profile is shown, where the inverter 37 "dwells", for example, 50-55 minutes each hour, and then gradually increases in speed from standstill to 15-20 meters/minute. The belts 18 move for from 5 to 10 minutes, or whatever other time empirical study has indicated will adequately clean the trash belts 18. The inverter 37 then gradually slows and finally stops for another 50-55 minutes.

Figure 6 illustrates that the belt 18 need not be started gradually, but can rapidly increase to the desired belt velocity.

Figure 7 illustrates that it may be desirable to start the belts 18 gradually, as in Figure 5, but need not be stopped gradually. Gradual start-up reduces the tendency of the sudden belt movement to shake loose or vibrate the trash off of the belts 18 and back into the air where it can be sucked into the yarn forming mechanisms, as described above. However, since the belts 18 are clean after the cleaning cycle, it makes little difference whether the belts 18 are stopped gradually or in the normal manner.

Figure 8 illustrates that the start-up can be made incrementally, with pauses at two or more intermediate belt velocities. This is another form of "soft start."

Figure 9 illustrates that the predetermined rates of belt velocity and the predetermined periods of time can vary considerably. For example, in Figure 9, the belt 18 is rotated for 30 minutes and stopped for 30 minutes, using the velocity profile shown in Figure 5.

The appropriate time interval of belt movement is determined by first observing the number of revolutions of the belt 18 necessary to adequately clean it. This is then converted into time and input through the keypad on the inverter 37.

Applicants have determined that in most cases the conventional belt velocity is approximately three times too high

without regard to the particular velocity profile used. Applicants have successfully designed and installed systems wherein the belts 18 are operated at approximately one-third the conventional belt velocity continuously with increased machine efficiency and yarn quality. This was accomplished by removing the belt pulley where the speed sensor is located and adding two more pick-up points. This causes the speed sensor to believe that the belts 18 are still rotating at the original speed.

An example of use of the method and apparatus is set out below:

Belt stopped time interval	30 minutes
Belt moving time interval	5 minutes
Belt velocity (meters/minute)	20 meters/minute
Inverter Model No.	GE AF-300M\$

The GE AF-300M\$ inverter, Catalog No. D5564, is a 380/460 V, 1HP Drive.

The rate of increase of belt velocity during "soft starts" is not critical, the point being to start the belt 18 sufficiently slowly to keep from shaking dust and trash into the air. It is believed that a "ramp up" to maximum belt velocity over 5-10 seconds fulfills this condition.

As noted above, the development of the invention took place on Schlafhorst SE-8 and SE-9 open-end spinning machines. The Schlafhorst SE-8 has a trash belt speed of approximately 40-45 m/m, and the Schlafhorst SE-9 has a trash belt speed of approximately 60-65 m/m.

More specifically, it has been determined that these trash belt speeds can be reduced as follows, based upon trash content:

Mostly heavy trash	approx. 30-40% of normal speed
Mostly medium trash	approx. 25-35% of normal speed
Mostly light trash	approx. 15-25% of normal speed
Evenly mixture of trash	approx. 20-30% of normal speed

Applicants have also determined that yarn count also affects the speed at which the trash belts 18 most efficiently operate. The majority of yarn counts range from a 5-6 heavy count, for example, denim used in manufacturing jeans, to a 35-40 light count used, for example, for the production of fine linens. Denim is usually woven of relatively cheap, dirty fiber, and this "roughness" is generally portrayed as desirable by the manufacturer. Linens, on the other hand, are generally produced from a much higher quality fiber, which has less trash in it to begin with. Therefore, the most efficient trash belt speed is determined by a further modification of the belt speed to take into account the yarn count. This has been determined to be in the range of 5-10%. To process heavier yarn counts, i.e., 5-6, belt speed would be increased by approximately 10%. Lighter yarn counts, i.e., 35-40, would process most efficiently by slowing the belt speed by up to 10%. Trials on counts between these ranges would suggest empirically an appropriate percentage increase or decrease in belt speed.

Examples

On a Schlafhorst SE-8 spinning machine:

Yarn Type	Trash Belt Speed (m/m)
5 count yarn for woven denim with heavy trash	18
5 count yarn for woven denim with medium trash	16
20 count yarn for shirtings with medium trash	8
40 count yarn for fine linens with light trash	6

On a Schlafhorst SE-9 spinning machine:

Yarn Type	Trash Belt Speed (m/m)
5 count yarn for woven denim with heavy trash	27
5 count yarn for woven denim with medium trash	24
20 count yarn for shirtings with medium trash	12

(continued)

Yarn Type	Trash Belt Speed (m/m)
40 count yarn for fine linens with light trash	9

With this type of analysis, it appears that the trash belt can be operated continuously but at a speed very substantially lower than was heretofore thought possible. These speed reductions can be carried out by use of differing motor pulley size or motor speed, or by placing an inverter in the electrical circuit whereby the speed can be set electronically.

A low-speed trash belt for open-end spinning machine method is described above. Various details of the invention may be changed without departing from its scope. Furthermore, the foregoing description of the preferred embodiment of the invention and the best mode for practicing the invention are provided for the purpose of illustration only and not for the purpose of limitation--the invention being defined by the claims.

Claims

1. A method of reducing trash recirculation into the fiber formation stream of an open-end spinning machine yarn formation station of an open-end spinning machine of the type having a movable trash belt which collects trash removed from sliver during yarn formation, said spinning machine having a predetermined, relatively high, conventional trash belt speed, characterised by the steps of:

(a) moving the trash belt at a low speed determined by the type of trash contained in the fiber, the type of yarn being spun and the type of fabric to be formed from the yarn, wherein said low speed is no more than substantially 50 percent of the conventional trash belt speed; wherein:

(b) the low speed of the trash belt is between substantially 15 and substantially 40 percent of conventional trash belt speed, with the low speed increasing as the proportion of heavy to light trash in the trash mixture increases;

(c) the method further includes varying the low speed of the trash belt a further plus or minus substantially 10 percent of the conventional trash belt speed, the low speed being increased up to substantially 10 percent of the conventional trash belt speed, the low speed being increased up to substantially 10 percent for fine yarns containing light trash with proportional variation in the percentage of increase or decrease proportional to the range of yarn size;

(d) altering the low speed of the trash belt to accommodate changes in trash mixture content, yarn size and yarn trash content; and

(e) cleaning the trash from the trash belt as the trash belt moves at the low trash belt speed.

2. A method according to claim 1, characterised in that said low speed of the trash belt is between substantially 5 and substantially 50 percent of the conventional trash belt speed.
3. A method according to claim 1 or 2, characterised in that said low speed of the trash belt is between substantially 20 and substantially 30 percent of the conventional trash belt speed.
4. A method according to claim 1, 2 or 3 characterised in that said low speed of the trash belt is between substantially 15 and substantially 25 percent of the conventional trash belt speed.
5. A method according to claim 1, characterised in that said low speed of the trash belt is between substantially 25 and substantially 35 percent of the conventional trash belt speed.
6. A method according to claim 1 or 5, characterised in that said low speed of the trash belt is between substantially 30 and substantially 40 percent of the conventional trash belt speed.
7. A method according to any preceding claim, characterised in that it includes the step of:
 - (e) providing a motor for controlling the rate of movement of the trash belt.

EP 0 893 518 A2

8. A method according to claim 7, characterised in that the step of providing a motor for controlling the rate of movement of the trash belt comprises the step of controlling the speed of rotation of the motor by applying a variable frequency to the motor.

5 9. Any novel subject matter or combination including novel subject matter disclosed herein, whether or not within the scope of or relating to the same invention as any of the preceding claims.
